Inhibition of human immunodeficiency virus type 1 replication by 2',5'-oligoadenylate analogs. 2',5'-Oligoadenylate analogs have been shown to inhibit human immunodeficiency virus type 1 (HIV-1) replication in vitro in a dose-dependent manner. Three analogs, 2',5'-oligo(A)14U, 2',5'-oligo(A)15U, and 2',5'-oligo(A)19U, are potent inhibitors of HIV-1 replication in peripheral blood mononuclear cells. Their inhibitory activities were comparable to that of 5'-oligo(A)14U. However, 2',5'-oligo(A)19U was more effective than 5'-oligo(A)19U in inhibiting HIV-1 replication. A maximum of 0.5 microgram of 2',5'-oligo(A)19U per ml inhibited virus replication to 10% of its control value. Similarly, a maximum of 0.5 microgram/ml of 2',5'-oligo(A)14U and 2',5'-oligo(A)15U inhibited virus replication to approximately 50 and approximately 20% of its control value, respectively. However, the inhibitory activity of 2',5'-oligo(A)19U was only 1 microgram/ml. The inhibitory effect of 2',5'-oligo(A)19U on HIV-1 replication was specific because it did not affect the replication of herpes simplex virus type 2, cytomegalovirus, and adenovirus. 2',5'-Oligo(A)19U did not inhibit cellular RNA synthesis. Our studies indicated that 2',5'-oligo(A)19U, 2',5'-oligo(A)14U, and 2',5'-oligo(A)15U are potent inhibitors of HIV-1 replication in vitro. Further studies are in progress to examine their in vivo effect. Is HIV self-testing really a smart move? A new study finds that people who take their own HIV tests are more likely to have new sexual partners, be incarcerated, or have sex with high-risk partners. Although HIV self-testing is supposed to empower individuals to detect their HIV status at the same time they learn they are HIV negative, it also opens them up to more risks.

Last year, I attended my first Apple event ever. The reveal of Apple's new iPad was a lot of fun, but I was also overwhelmed with excitement for the new operating system. With that release came the introduction of iOS 8. After an initial review, I found it to be more powerful than I was expecting. I knew that there was an update coming, but it was initially planned for a release just before the iPhone 6 launch. I was not prepared for the changes that were being made to the iPhone and iPad OS. The real change to iOS 8 for me was the Music app. I've been an avid Spotify user for several years, and I enjoy the many benefits of the service. Last year, I wrote a full review of how I use Spotify, which you can read [here](#). In my research for a new Spotify alternative for the iPad, I stumbled across Groove Music. The service looked amazing on paper and seemed to fit the functionality of Spotify while being much more accessible. I decided to investigate and test out Groove Music for the iPad. I'm a true fan of Spotify, but I felt that they weren't working hard enough on the iPad. On the phone, I am able to read full articles or listen to Spotify on the go. With Groove Music, I was able to read articles while listening to music, and had access to everything with a simple tap. I also had access to all my playlists in the Groove Music app. These changes were a big plus for the iPad. I started using Groove Music for my main music player. For anyone who loves Spotify, Groove Music has a few things to like as well. For instance, I was able to take advantage of the in-app podcast player. Spotify has the ability to support podcasts, but Groove Music has integrated a great podcast player. I wasn't expecting this functionality, and now I don't have to jump to another app to listen to podcasts. Spotify is still my main streaming music platform, but I love the many features of Groove Music. The experience is a bit more limited than that of Spotify, but it makes up for that with the amount of functionality it offers. What do you think of Groove Music? Let us know in the comments.
